## Problem 1

### Membership in NP

A problem is in NP if there exists a certificate for a "yes" instance of the problem that can be verified in polynomial time. For the Star Problem, a subgraph  $H \subseteq G$  claimed to be a shooting star with  $2r$  vertices. To confirm that  $H$  contains exactly  $2r$  vertices, we need to check that exactly  $r$  of these vertices form a clique and verify that the remaining  $r$  vertices form a path, which is connected to one of the clique's vertices.

These verification steps are computationally basic and can be executed in polynomial time, confirming that STAR is in NP.

#### NP-Hardness

To establish that the Star Problem is NP-hard, we perform a polynomial-time reduction from the CLIQUE problem, which is known to be NP-complete.

### Reduction Process

1. **Given Instance:** Take a graph  $G = (V, E)$  with a clique number  $k$  from the CLIQUE problem.
2. **Constructing an Instance of Star Problem:**
  - Utilize the vertices  $V$  and edges  $E$  from  $G$ .
  - Add  $k$  new vertices  $\{u_1, u_2, \dots, u_k\}$ , to form a path.
  - Connect  $u_k$  to each vertex in  $V$ , enabling potential attachment to any clique in  $G$ .
  - Set  $r = k$  in the Star Problem.
3. **Reduction Validity:**
  - **If CLIQUE has a solution:** A clique of size  $k$  in  $G$  combines with the path of new vertices to form a shooting star of size  $2k$  in the new graph.
  - **If Star Problem has a solution:** The clique portion of the shooting star must correspond to a clique of size  $k$  in  $G$ , verifying the clique solution.

The polynomial-time reduction from CLIQUE to the Star Problem indicates that solving the Star Problem is at least as difficult as solving the CLIQUE problem. Since CLIQUE is NP-complete, this implies that the Star Problem is also NP-hard. Combining its NP membership and NP-hardness confirms that the Star Problem is NP-complete.

## Problem 2

We propose a brute-force algorithm, Algorithm A, to determine if at least  $k$  rectangles overlap. This algorithm checks all pairs of rectangles to identify overlapping pairs, a task that involves  $O(n^2)$  operations since each pair comparison requires  $O(1)$  time. Thus, the overall time complexity is polynomial, and we conclude that  $\text{RECTANGLE} \in \text{P}$ .

To prove  $\text{RECTANGLE}$  is polynomial-time reducible to  $\text{CLIQUE}$  ( $\text{RECTANGLE} \leq_p \text{CLIQUE}$ ), we note that any problem in  $\text{P}$ , including  $\text{RECTANGLE}$ , can be reduced to any  $\text{NP}$ -complete problem such as  $\text{CLIQUE}$ . This is because solving  $\text{RECTANGLE}$  directly in polynomial time allows us to construct an instance of  $\text{CLIQUE}$  that is trivially solvable if  $\text{RECTANGLE}$  is solvable.

### Specific Reduction

We can create a more explicit reduction to demonstrate how  $\text{RECTANGLE} \leq_p \text{CLIQUE}$ :

- Construct a graph where each vertex represents a rectangle.
- Add an edge between two vertices if their corresponding rectangles overlap.

In this graph, a clique of size  $k$  represents a set of  $k$  rectangles where each overlaps with all others in the set. This mapping directly translates an instance of  $\text{RECTANGLE}$  into  $\text{CLIQUE}$ :

1. Construct vertices for each rectangle in  $R$ .
2. Connect vertices with edges if their rectangles overlap, requiring  $O(n^2)$  pairwise comparisons.

This transformation is polynomial in time, ensuring that solving the  $\text{CLIQUE}$  problem with this graph also solves the  $\text{RECTANGLE}$  problem.

Given  $\text{RECTANGLE} \in \text{P}$ , it is also in  $\text{NP}$  since any problem in  $\text{P}$  is also in  $\text{NP}$ . As  $\text{RECTANGLE}$  is in  $\text{P}$  and we assume  $P \neq \text{NP}$ ,  $\text{RECTANGLE}$  cannot be  $\text{NP}$ -complete unless  $P = \text{NP}$ . From the reduction  $\text{RECTANGLE} \leq_p \text{CLIQUE}$  and knowing  $\text{RECTANGLE} \in \text{P}$ :

- $\text{CLIQUE}$  is at least as hard as  $\text{RECTANGLE}$ .
- Since anything in  $\text{P}$  can be as easy or easier than  $\text{RECTANGLE}$ , this does not imply  $\text{CLIQUE} \in \text{NPC}$  based on this reduction alone.

Note: While we know  $\text{CLIQUE} \in \text{NPC}$ , this analysis by itself does not lead us to that conclusion independently of known results.
